

CHEM131 HOMEWORK #5 KEY

- 4-40. The titration data and knowing that there is just 1 acidic H in carminic acid (CA) allows us to calculate the molar mass of CA.

$$(0.0406 \text{ mol NaOH/L sol})(18.02 \times 10^{-3} \text{ L sol}) = 7.32 \times 10^{-4} \text{ mol NaOH} = 7.32 \times 10^{-4} \text{ mol CA}$$

in 0.3602 g

$$\text{molar mass of CA} = (0.306 \text{ g}) / (7.32 \times 10^{-4} \text{ mol CA}) = 492 \text{ g/mol CA.}$$

We also know CA is 53.66% C, 4.09% H, and 42.25% O, and in principle this info permits calculation of the empirical formula. BUT 492 is a quite large molar mass; depending on how many H atoms are present, there could easily be 50 atoms in one molecule of CA! Chances are good that the usual procedure of looking for simple mole fractions will give ambiguous results. Let's start with the usual 100 g sample.

$$53.66/12.011 = 4.468 \text{ mol C}; 4.09/1.008 = 4.06 \text{ mol H}; 42.25/15.999 = 2.641 \text{ mol O}$$

Dividing each by the smallest to get C:H:O gives 1.692:1.54:1, and indeed it is not obvious what the common multiplier should be. A brute force approach works, just try every number until you find one that works, but this is a procedure that is best done with a computer spreadsheet program, such as Excel. A quite useful clue is gained by noting that the 4.468 C number is very nearly 10% larger than the H number, $4.468/4.06 = 1.101$ or 4.468 is 11 times larger than 0.406. Dividing each number by 0.406 gives 11:10:6.50 or 22:20:13. The empirical formula is $\text{C}_{22}\text{H}_{20}\text{O}_{13}$. $22 \times 12 + 20 \times 1 + 13 \times 16 = 492$ and the empirical formula is correct.

- 4-42. $(0.1082 \text{ g KHP}) / (204.22 \text{ g KHP/mol KHP}) = 5.298 \times 10^{-4} \text{ mol KHP} = 5.298 \times 10^{-4} \text{ mol NaOH}$

$$(5.298 \times 10^{-4} \text{ mol}) / (34.67 \times 10^{-3} \text{ L}) = 1.528 \times 10^{-2} \text{ M}$$

- 4-44. $\text{mol H}_3\text{PO}_4 = (14.2 \times 10^{-3} \text{ L})(0.141 \text{ mol/L}) = 2.002 \times 10^{-3} \text{ mol}$. Since phosphoric acid has 3 acidic protons per molecule, we know $\text{mol H}^+ = 3 \times \text{mol H}_3\text{PO}_4 = 6.007 \times 10^{-3} \text{ mol H}^+$. For exact neutralization $\text{mol H}^+ = \text{mol OH}^-$ so $\text{mol OH}^- = 6.007 \times 10^{-3} \text{ mol}$.

However, Ba(OH)_2 has 2 OH^- per molecule, so $\text{mol Ba(OH)}_2 = (1/2) \times \text{mol OH}^- = 3.003 \times 10^{-3} \text{ mol}$.

If we have a volume V, the mol of $\text{Ba(OH)}_2 = V \times 0.0521 \text{ M Ba(OH)}_2$. Solve for V: $V = 3.003 \times 10^{-3} \text{ mol} / (0.0521 \text{ mol/L}) = 57.6 \text{ mL of solution}$.

- 4-49. $(75.0 \times 10^{-3} \text{ L})(0.250 \text{ mol H}^+/\text{L}) = 1.875 \times 10^{-2} \text{ mol H}^+$

$$(225.0 \times 10^{-3} \text{ L})(0.0550 \text{ mol Ba(OH)}_2/\text{L})(2.000 \text{ mol OH}^-/\text{mol Ba(OH)}_2) = 2.475 \times 10^{-2} \text{ mol OH}^-$$

$$2.475 \times 10^{-2} - 1.875 \times 10^{-2} = 6.0 \times 10^{-3} \text{ mol OH}^- \text{ in 300 mL solution}$$

$$(6.0 \times 10^{-3} \text{ M OH}^-) / (300 \times 10^{-3} \text{ L}) = 2.0 \times 10^{-2} \text{ M OH}^-$$
